TM II-620

RADIO SETS

SCR-608-A AND SCR-628-A

WAR DEPARTMENT • 1 JANUARY 1944

SECTION V. SUPPLEMENTARY DATA

42. Replacement of Parts.

a. Mounting FT-237-(*)�

(1) Method of Removing Coaxial Cables from L and T Connectors.

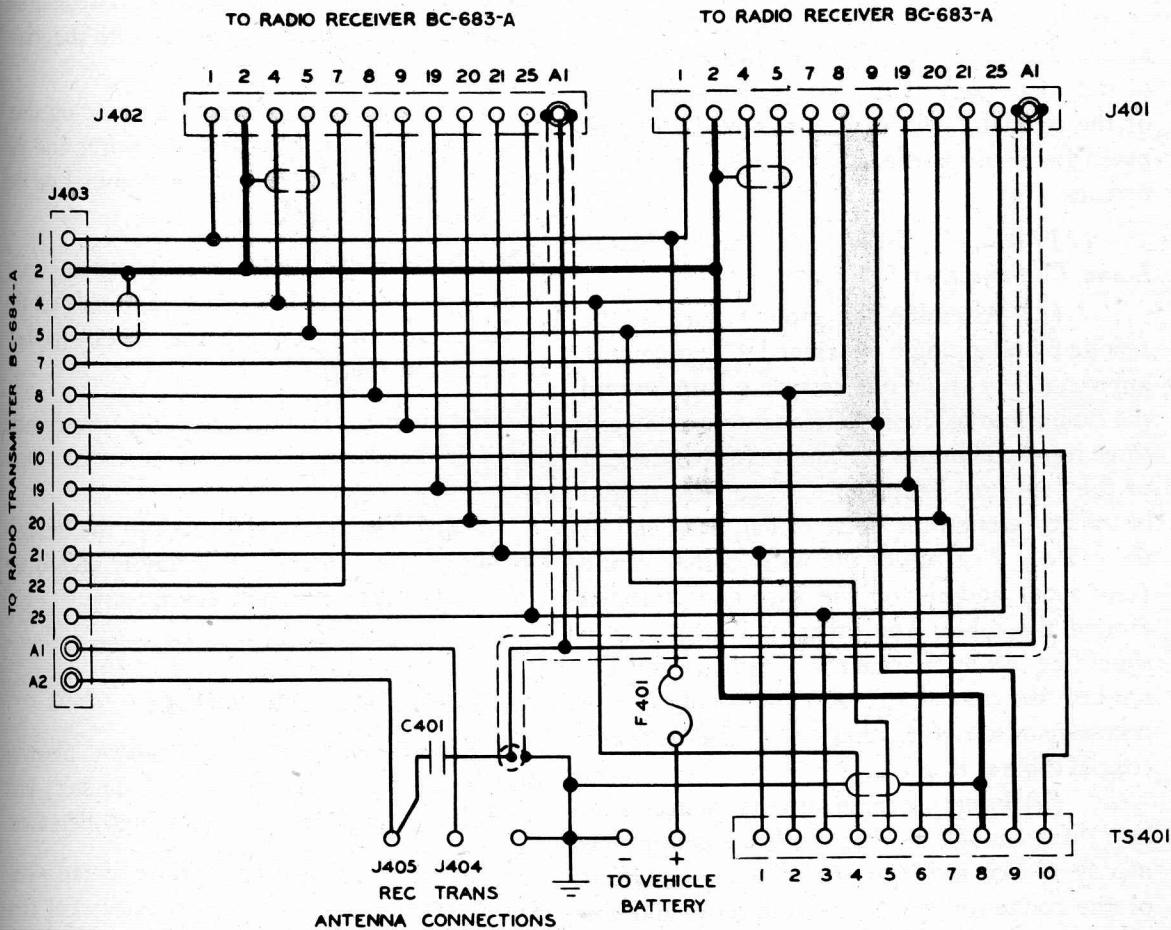

(a) Remove the covers from the rear and end channels of the mounting.

(b) Unsolder at the ground clips the ground wires running from the ferrule of the coaxial cable to the ground clips in the channel;

remove the varnished sleeving and bend the wires back from the channel.

(c) Remove the cover clips from the connectors and unsolder the connections inside the connectors.

(d) Loosen the Bristol set screw on the under side of the connectors, cut the tie strings which hold the coaxial cable in position, and pull out the coaxial cable and connectors from the rear channel.

Fig. 61. Mounting FT-237-(*)�: Schematic Diagram

(e) Cut the tie strings holding the coaxial cable in position in the end channel, unsolder the connection between the coaxial cable and the capacitor, remove the screw and nut from the coaxial cable ground clamp, and pull out the coaxial cable from the end channel.

(f) With the connector held in a pair of gas pliers in the left hand, place the connector against the tip of a 200-watt soldering iron (held stationary), and remove the cable from the connector by pulling with the right hand when the solder in the connector has been heated sufficiently to become fluid. Remove the excess solder from the connector by tapping it while hot against a solid object. (This permits ready re-use of the connector). The ground clip at the end of the coaxial cable may be removed and prepared for re-use in the same manner as for connectors.

(2) Method of Soldering Coaxial Cables to L and T Connectors.

(a) Assemble the ground wire to the ferrule by wrapping bare, tinned 22-gauge wire approximately three quarters of a turn around the cable close to the ferrule and approximately three turns around the ferrule as close to the end of the ferrule as practicable. (The wire should be twisted around the open, or flat, bead end of the cable.) Spot solder the wire to the ferrule (one spot) and cut off the wire end wrapped around the cable. The other end of the wire should be left approximately 3 inches long. Do not heat the coaxial any more than is absolutely necessary to solder it, otherwise the beads in the coaxial cable will soften.

(b) Insert the cable into the connector (L or T) far enough so that the bead is approximately $\frac{1}{16}$ -inch inside of the milled-out portion of the connector. Hold the connector and the cable in a vertical position; solder the ferrule of the cable and the ground wire to the connector, using a 200-watt soldering iron. Avoid unnecessary heating of the cable.

(c) With the cable in a horizontal position, solder the ground clamp to the ferrule at the end of the cable. To avoid twisting the cable, solder the ground clamp at approximately 90

degrees to the long axis of the portion of the connector having the Bristo set screw.

(d) Place the cable in a position adjacent to and approximately parallel with the rear channel. Assemble the varnished tubing on the ferrule ground wires and connect and solder the ground wires to the ground clip at the J401 and J402 receptacles.

(e) Place the coaxial cable in the channel, push the connectors into position on the radio-frequency terminals of the J401 and J402 receptacles, and tighten the Bristo set screws with a $\frac{3}{16}$ -inch Bristo hexagonal wrench. Assemble the ground clamp in the end channel with the screw and nut.

(f) Inside the connectors, twist together, solder, and clip the coaxial cable wires and the wires from the radio-frequency terminal on the J401 and J402 receptacles.

Note: Be sure the beads are in position on the wire from the radio-frequency terminals on the receptacles before twisting the wires together. If necessary, replace the beads.

Twist together, solder, and clip the coaxial wire and the capacitor terminal in the end channel.

(g) Tie the coaxial cable to the hexagonal nut of the plunger pin assembly and to the local cable (approximately seven ties).

(h) Replace the channel covers.

b. Radio Receiver BC-683-A.

(1) *Replacement of a Channel Selector Unit.* To replace a channel selector (tuner) unit in a receiver, perform the following operations.

(a) *Connections to be Unsoldered.*—Unsolder seven (sometimes eight) electrical connections at the tuner unit (channel selector) to release it from other receiver apparatus.

(b) *Screws to be Removed.*

(1) Remove the four screws releasing the front guard of the receiver.

(2) Remove the eight screws releasing the front panel.

(3) Loosen the five screws in the rear

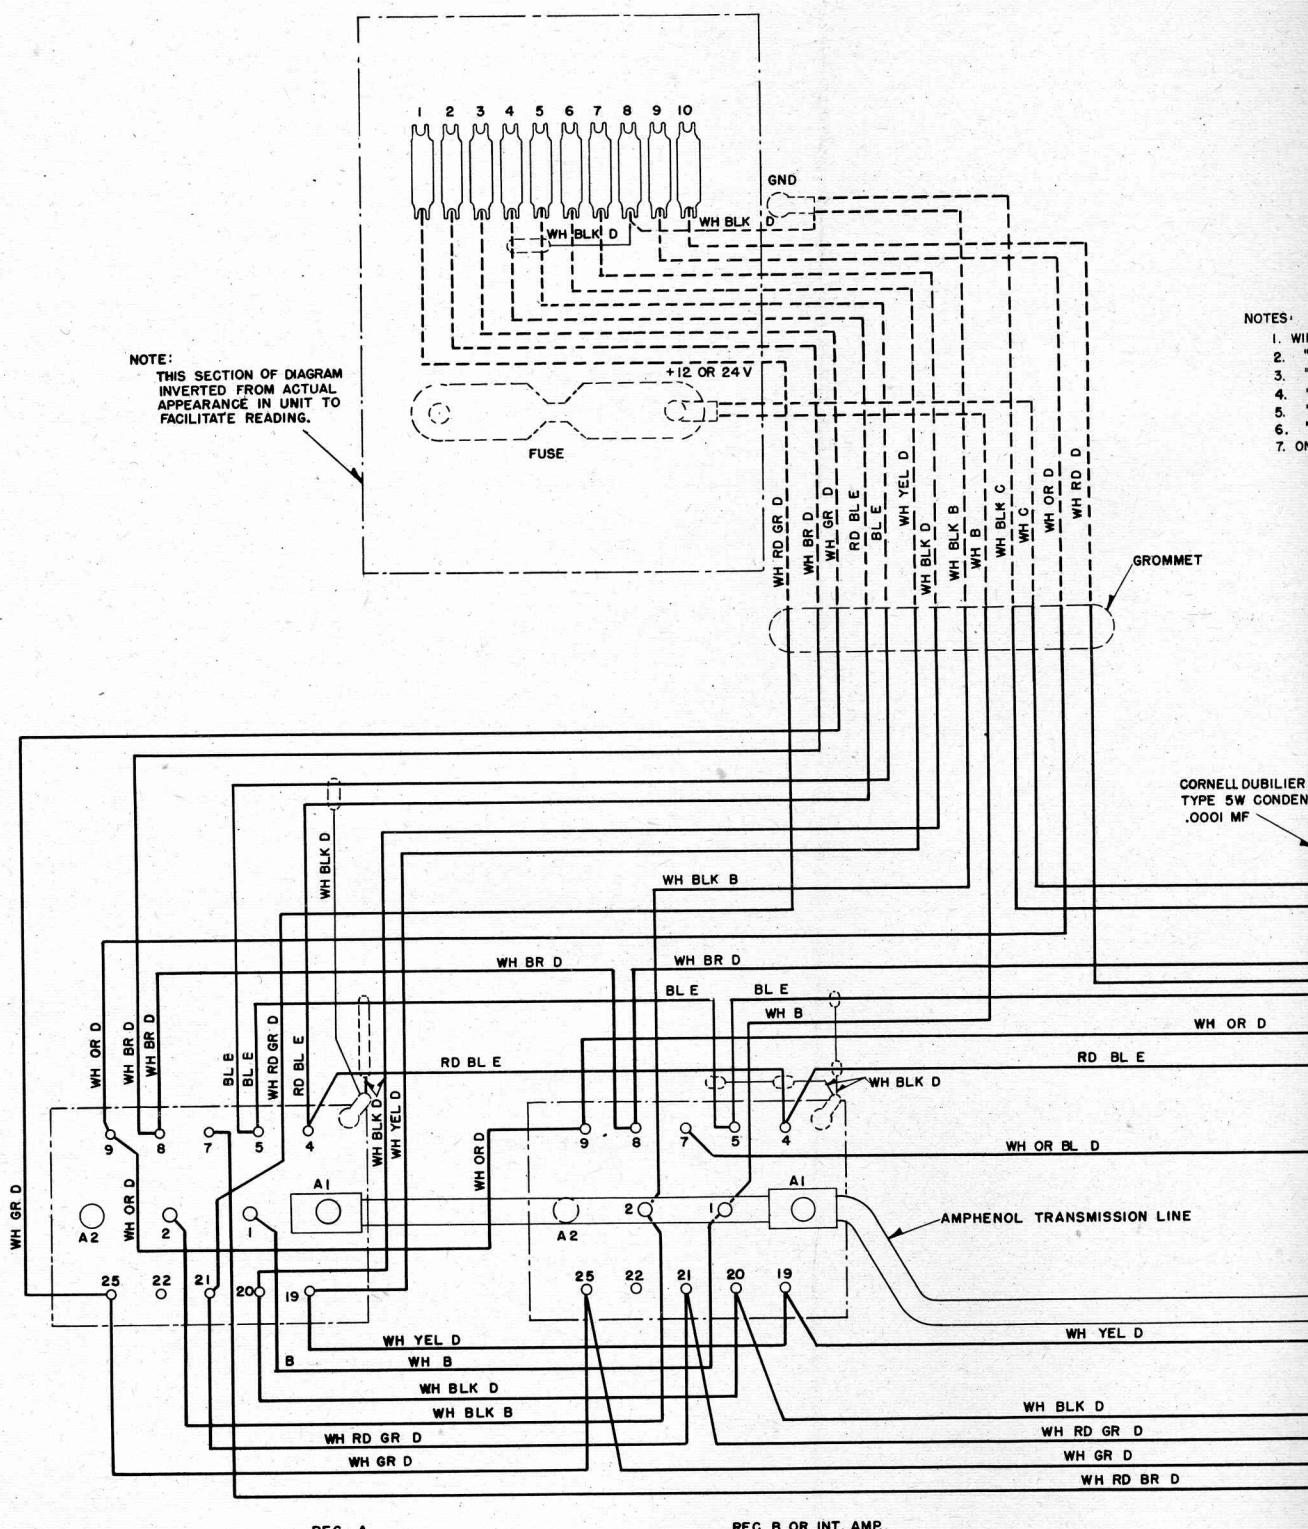

Fig. 62. Mounting FT-237-(*): Wiring Diagram

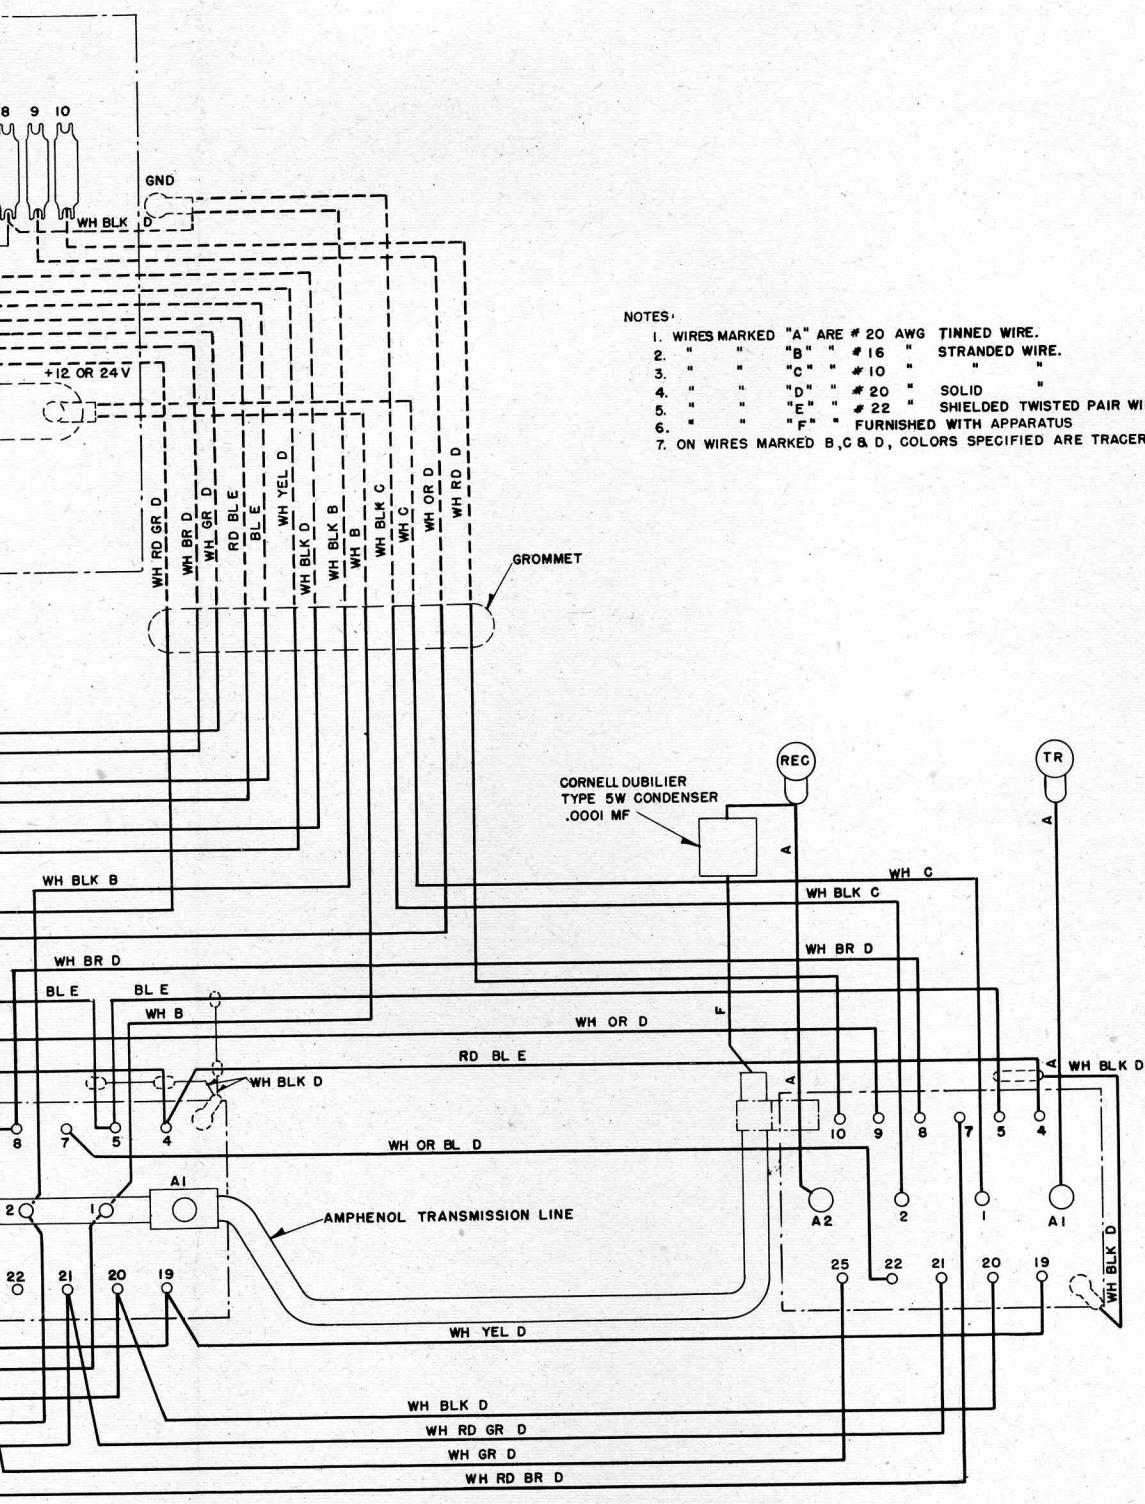

Fig. 62. Mounting FT-237-(*): Wiring Diagram

of the tuner, releasing the tuner unit from the receiver chassis.

(c) Method of Replacing Channel Selector.

(1) With the front panel guard and front panel removed from the receiver, insert the tuner unit through the front panel opening into the chassis.

(2) Loosely fasten the unit to the chassis by five screws. *Do not tighten these screws.* See operation (5) for tightening.

(3) With the tuner loosely in place add the front panel with its apparatus, and fasten securely to the chassis (six screws) and the tuner unit (two screws).

(4) Add the front panel guard to the receiver, secure it firmly with four screws.

(5) Supplement operation (2) by securing the tuner firmly to the chassis with the five screws in the rear of the tuner. Be sure to follow this procedure of fastening the five rear screws as it avoids setting up a strain while tightening the two front screws which hold the tuner in position. (The six other screws which hold the front panel do not affect the tuner.) Such possible strain might permanently impair the accuracy of the tuner. Check to see that all push buttons operate smoothly and do not bind on the receiver panel.

(6) Resolder the seven (sometimes eight) electrical connections at the tuner unit.

(2) Replacement of a Push-button (Plunger) Assembly in a Channel Selector.

(a) Release the push button setting as described in Paragraph 21b. Release all push buttons.

(b) Screw Removal Operation.

(1) Remove four screws to release the front panel guard.

(2) Remove eight screws to release the front panel.

(3) Remove four flathead screws to release the tuner front plate and the latch-plate assembly.

(c) Removal of Latch-plate and Push-button Assembly.—Pull the lower end of the latch-plate assembly outward slightly. Grasp the

edges of the latch plate just behind the face plate and pull the latch plate downward. Pull the entire assembly outward gently to prevent jamming, and nurse the top end of the latch plate past the edge of the mounting bracket. Pull the assembly further until it separates from the connecting rods.

(d) Substitution of Push Button.—With the push buttons hanging downward, pull the latch plate back against its spring. Remove the faulty button and replace it with a new button making sure that the notch is in line with the notch on other buttons. Allow the latch plate to return to normal.

(e) Replacement of Latch-plate and Push-button Assembly.—Line up the latch-plate assembly with the connecting rods. Release the latch plate and mesh each button separately, starting at the top. When all are properly meshed, pull all buttons forward so that the latch plate can release and hold them. Push the assembly into place carefully by nursing the latch plate past the mounting bracket while the latch plate is pulled down. When it is in position, release the latch plate and replace the flathead screws to hold it in place. Replace the front panel and the front panel guard. Set the push buttons for the desired channels as described in Paragraph 21b.

c. Radio Transmitter BC-684-A.

(1) Replacement of a Channel Selector Unit. To replace a channel selector (tuner) unit in a transmitter, perform the following operations.

(a) Connections to be Unsoldered.

(1) Unsolder the short and long coaxial cables at antenna post A on the rear of the front panel. Also unsolder R155 from this post.

(2) Unsolder the short coaxial cable at the antenna relay S101.

(3) Unsolder at the relay (S101) the capacitor (C161) which connects a long coaxial cable to this relay.

(4) Unsolder, at the relay, the bare wire which connects the top of the L111 coil to the antenna relay.

(5) Unsolder, at the bottom of the L110 output coil, the bare wire (covered with varnished tubing) which leads to the power amplifier screen resistor (R114) located in the bottom compartment of the chassis. Also unsolder the black-red wire leading from the coil to the local cable of the transmitter.

(6) Unsolder, at the insulated stud E, the bare wire leading to the bottom of the left-hand tuner contact spring assembly.

(7) Unsolder, at the crystal oven, the ten electrical connections to the tuner spring contact assembly.

(b) Screws to be Removed.

(1) Remove the screw on top of the selector to release the ground terminal lug and wire leading to ground post G on the rear of the front panel.

(2) Remove six screws from the thermocouple, releasing it from its electrical connections and mounting.

(3) Remove the screw which secures the ground lug to the top of the tuner,—the lug to which the ground wires leading to the short and long coaxial cables ferrules are connected.

(4) Remove the screw from the top of the tuner, releasing the clamp that holds the long coaxial cable in place across the top of the unit. Carefully bend this cable to the left so that it will not interfere with vertical movement of the tuner.

(5) Remove four screws, releasing the antenna relay (S101) from its location. Rotate the relay upward and to the right.

(6) Remove the gear from the bottom end of the tuner shaft by loosening the set screws with the Bristo wrench, and remove the rack connecting the tuner to the six-gang capacitor.

(7) Remove the three screws at the base of the tuner, releasing it from the chassis.

(8) Remove the four screws in the panel guard and remove the guard; unscrew the seven front panel screws and rotate the panel about its right-hand edge (where cables are located) to remove the panel apparatus from the panel opening. Lift the channel selector unit out through the top opening of the transmitter.

(c) Method of Replacing Channel Selector.

(1) With the front panel guard removed and the front panel swung out of the way, insert the selector unit into the chassis through the top opening of the transmitter.

(2) Loosely fasten the unit to the chassis by the three screws applied into the base of the selector through the bottom opening of the transmitter.

(3) Repeat, in reverse order, the remaining steps of (a) and (b) preceding with the exception of (b)(6).

Caution: When fastening the tuner firmly in position (after the front panel and its apparatus have been secured to the transmitter), observe that the tuner shaft rotates freely; if it does not, loosen the three mounting screws and shift the tuner until the tuner shaft is free to rotate without binding action. When locating the front panel and the tuner in position, be sure the push buttons do not rub in the panel openings.

(4) With the six-gang capacitor fully engaged and the pin (on the disk by which this capacitor is manually rotated) resting against the front stop in the semicircular opening in the right end of the chassis, and with the single-section tuning capacitor at the top of the tuner also fully closed (maximum capacitance), insert the gear on the tuner shaft, assemble the rack in place, and securely tighten the set screw on the gear. Note that the rack is centrally located and that it moves freely back and forth over its total travel.

(2) *Replacement of Capacitor Assembly (Including Six-gang Capacitor and Trimmer Capacitors).* To replace a capacitor assembly in a transmitter, perform the following operations.

(a) *Connections to be Unsoldered.*—Unsolder, through the bottom opening of the transmitter, all wires connecting to the six-gang capacitors.

(b) Screws to be Removed.

(1) Remove, at the left-hand end of the gang capacitor, the screw which holds a bracket and insulated terminal in place.

(2) Through the bottom of the transmitter remove four screws from the trimmer capacitor assembly bracket, releasing the entire capacitor assembly from the chassis.

(c) Replacement of Capacitor Assembly.

—Remove the capacitor assembly, replace with a new unit, and reassemble in reverse order from (a) and (b).

(3) *Replacement of Gang Capacitor in the Gang-capacitor Assembly.*

(a) Repeat operations of (2)(a) and (2)(b) preceding to release the entire capacitor assembly from the transmitter chassis.

(b) Unsolder all electrical connections between the six-gang capacitor assembly and the trimmer capacitors.

(c) Remove four elastic stop nuts on the six-gang capacitor assembly to release the bracket on which the associated trimmer capacitors are mounted.

(d) Separate the six-gang capacitor from the trimmer capacitor assembly bracket released by the stop nuts.

(e) Replace the six-gang capacitor with a new unit and reassemble, with the trimmer capacitor assembly, into the transmitter chassis.

(4) *Replacement of Trimmer Capacitor Assembly.*

(a) Repeat the operations of (3)(a) and (3)(d) preceding.

(b) Replace the trimmer capacitor section with a new unit and reassemble, with the six-gang capacitor assembly, into the transmitter chassis.

(5) *Replacement of a Push-button (Plunger) Assembly in a Transmitter Channel Selector.*
To replace a channel selector push button in a transmitter, perform the following operations.

(a) Unsolder the long and short coaxial cables at antenna post A on the rear of the front panel.

(b) Remove the screw from the frame at the top of the selector unit to release the ground terminal wire leading to ground post G on the rear of the front panel.

(c) Remove the tie-string which supports the short coaxial cable in the position near the left-hand post of the panel meter.

(d) Remove the four screws holding the front panel guard.

(e) Remove the seven screws holding the front panel and rotate the panel outward about its right-hand edge.

(f) Remove the four screws on the tuner front plate and latch-plate assembly in order to release the push buttons.

(g) Pull the defective plunger (push button) forward to separate it from its associated rod.

(h) Replace plunger and reassemble.

(6) *Removal of Tuning Coils in Low Power Stages.*

(a) Unsolder the leads to the upper and lower terminals of the defective coil winding (L106, L107, L108, L118, or L119).

(b) Break the Glyptal seal at the bottom of the cylindrical metal tube in the top compartment.

(c) Unscrew the metal tube from the coil form.

(d) Remove the coil winding assembly from the chassis by withdrawing it from its location hole into the bottom compartment of the transmitter.

(7) *Removal of Coaxial Cable Terminals from Plug PG101.*

(a) Unsolder the ground straps between the coaxial cable ferrules and the chassis.

(b) Remove two screws and hexagonal nuts from each end of the plug to release the two metal plates (clamps) that hold the cable terminals in place.

(c) Remove the metal clamps and pull the cables and terminals from their locations in the plug.

43. *Modifications during Manufacture.*

a. *General.* The radio equipment described in this manual has been produced in large quantities over a relatively long period of time. Dur-

ing this period the equipments have been under continual study in the manufacturing plants and in the field. Some changes in the equipment have resulted from these studies. By far the greatest number of changes has been due to the necessity of using a different material, or a part from a different manufacturer. In general, you will find that the units which comprise your radio set will differ in some slight respect from other similar units bearing the same order number.

This apparatus has not only been made in large quantities but also has been constructed by a number of different subcontractors, which means that there may be minor differences in construction or parts. Watch for these variations although in most cases they will not affect servicing procedure.

Changes in materials or in the source from which similar parts are obtained do not in general affect the servicing procedure, so this type of change is not described in this manual. Circuit and apparatus changes which should be known to aid the proper servicing of the unit are described in some detail in Paragraph 43b for the receiver and Paragraph 43c for the transmitter.

Figure 70 is a schematic diagram of the receiver showing how it was before these changes were made. The parts that have been changed are crossed out and the new arrangements shown. Figure 73 gives corresponding information for the transmitter.

If you wish to make any of these changes in an earlier equipment and if the change has been authorized, all the items listed under a particular minor heading in the change must be made as a group in order to obtain the desired improvement.

b. Radio Receiver BC-683-A.

(1) *Changes Affecting R17 and R19.* R17 has been changed from 1 megohm to 0.25 megohm. R19 has been changed from 1 megohm to 2 megohms. The purpose of this change was to increase the voltage on the CALL SIGNAL lamp.

(2) *Changes Affecting L72 and L71.* In earlier drawings these two inductors were shown interchanged. L72 should be the primary wind-

ing in the plate circuit of V5. L71 should be the secondary winding in the grid circuit of V6.

(3) *Changes Affecting C11.* C11 has been reduced from 0.01 to 0.006 microfarad. The purpose of this change was to reduce the number of 0.01-microfarad capacitors.

(4) *Changes Affecting C82 and C20.3.* C82 has been reduced from 0.01 to 0.006 microfarad. C20.3 has been connected in parallel with C82. (It was previously in parallel with C20.2.) The purpose of this change was to reduce the number of 0.01-microfarad capacitors. It was found that the audio-frequency impedance of the circuit at the points across which C82 is connected should be reduced to improve circuit operation. This was accomplished by connecting C20.3 across C82 after which C82 could be reduced. It was found, also, that when C20.3 was so connected, the stability of the circuit was better than it had been with C20.3 connected across C20.2.

(5) *Changes Involving R8, R21, R71, R72, R74, and C71 (Limiter Characteristics of V5).*

R8 has been increased from 20,000 to 70,000 ohms ($\frac{1}{2}$ -watt type).

R21, which is a 30,000-ohm (2-watt) type, has been added.

R71 has been increased from 100,000 ohms to 250,000 ohms.

R72 has been decreased from 43,000 ohms to 30,000 ohms.

R74 has been decreased from 10,000 to 1,000 ohms ($\frac{1}{2}$ -watt type).

C71 has been decreased from 100 to 50 micromicrofarads.

These wiring changes were desirable because, on very strong signals, the output of the limiter previously fell off so much as to interfere with the operation of the squelch circuit under some conditions. In addition, the changes improved the reception of weak signals through high noise levels. In general, the changes were:

To make the second intermediate-frequency amplifier, V5, a more effective limiter by lowering screen and plate voltages. This involves R8 and R21 and a change in the plate return of V5. R74, formerly 10,000 ohms, could be reduced to 1000 ohms as drop in this resistor was no longer re-

quired. R71 was increased to improve the limiting action. This necessitated reducing C71 to maintain the proper time constant. R72 was decreased to obtain optimum load cross L71.

To remove the second intermediate-frequency amplifier from the influence of the delayed-automatic-volume-control circuit. This improved reception through strong noise. It involved moving the grid return of V5 from the automatic-volume-control circuit to the negative end of the dynamotor.

These changes are indicated graphically in Fig. 70 which shows the old arrangement crossed out and the new arrangement added.

The actual changes in wiring are as follows:

- (a) Move one pigtail of R8 from terminal 5 of FL2A to terminal 2 of FL2A.
- (b) Remove a wire (covered with a black sleeve) from terminal 6 of VS5 and terminal 5 of FL3A.
- (c) Connect one pigtail of R21 to terminal 5 of FL2A and the other pigtail to terminal 5 of FL3A.
- (d) Remove the green (tracer) wire from terminal 4 of VS9 and connect it to that terminal of C25 to which the blue (tracer) leads are connected.
- (e) Add a blue-brown (tracer) wire from terminal 5 of FL3A to terminal 5 of FL4.

(6) *Change Involving C44.* This 30-micro-microfarad capacitor in the radio-frequency oscillator circuit was changed from silver mica to an N-080 Ceramicon. The change was made to improve temperature stability.

(7) *Change Involving C26.* C26 has been reduced from 0.001 to 0.0005 microfarad. This was done to permit the use of a ceramic capacitor as an alternate. This change also improved the operation of the beat oscillator by reducing the pull-in at low frequencies.

(8) *Changes in Capacitors of Dynamotors.* In Dynamotors DM-34-(*) and DM-36-(*), all the filter capacitors in some units have been reduced from 0.005 to 0.003 microfarad. No reduction in circuit performance results from this

change. Where a replacement problem involves a substitution of a filter capacitor, either a 0.003 or a 0.005-microfarad unit may be used in any position in the dynamotor without regard to the capacitance of the remaining units, but the replacements must meet the voltage rating prescribed in Paragraph 45, Table of Replaceable Parts.

(9) *Change in C35.* This unit was reduced from 0.01 to 0.006 microfarad.

(10) *Changes Affecting C53, C54, C55, C56, C63, C64, C65, C66, C73, C74, C75, C76, C84, C85, C86, C87, C88.* These changes are tabulated as follows:

Filter	Original Unit	Capacitance Value	
		Original	Replacing
FL1A	C53 and C54	*50 + †10	‡60
FL1A	C55 and C56	†10 + *50	‡60
FL2A	C63 and C64	*50 + †10	‡60
FL2A	C65 and C66	†10 + *50	‡60
FL3A	C73 and C74	*50 + †10	‡60
FL3A	C75 and C76	†10 + *50	‡60
FL4	C84, C85, and C86	†5, *50, and *50	‡60 and ‡60
FL4	C87 and C88	*25 + †10	‡35

*Silver-mica.

†Ceramic N-680.

‡Ceramic N-080.

In filter units FL1A, FL2A, FL3A, and FL4 of the receiver, small ceramic capacitors were used originally in combination with silver-mica capacitors to provide temperature-compensated tuning capacitances. In later equipments these combinations of two capacitors have been replaced by single ceramic units each having capacitance and temperature compensation equal to those of the combination which it replaced. This is possible because a ceramic capacitor can be provided with any desired temperature coefficient (over a substantial range of positive and negative values). The single ceramic capacitor may be used as a direct replacement for the combination or vice versa. All the changes listed here fall in this class. Most of them are combinations where two units were in parallel and the changes involved a single ceramic with capacitance equal to the sum of the two and a temperature coefficient equivalent to their combination. In FL4, however, C85 and C86 (each a 50-micromicro-

farad silver-mica capacitor) were in series and C84 (a 5-micromicrofarad Ceramicon) was in parallel with the combination, making a total of 30 micromicrofarads. C85 and C86 have been changed to 60-micromicrofarad Ceramicons with the desired temperature coefficient which makes C84 unnecessary.

(11) *Change in Designation of Switch D2.* Switch D2 on the receiver was originally designated RADIO & EXT-EXT ONLY. This designation was changed to OUTPUT TO PHONES ON-OFF to provide a better conception of the function of this switch.

(12) *Change to Sealed Unit LCU3-C.* LCU3-C units are sometimes supplied as spare parts in place of LCU3-A units to replace the LCU3-A oscillator unit. The LCU3-C unit is essentially the same as the LCU3-A unit, except that it has been sealed to exclude moisture, thereby improving frequency stability of the receiver under high humidity conditions. The terminal numbers molded in the bakelite seals of the LCU3-C unit correspond to the terminal numbers of the unsealed LCU3-A unit.

If difficulty is encountered with frequency stability of a receiver under high humidity conditions, replace the LCU3-A unit with an LCU3-C sealed unit as follows:

Wire the LCU3-C unit in place without disturbing the cap. The adjustable slug of the LCU3-C unit has been preset at the factory and should seldom require adjustment during the alignment procedure. The capacity trimmer C1.7 should be adjusted for dial tracking at 38 megacycles and the dial tracking checked at 28, 32, and 35 megacycles. In many instances a slight readjustment of C1.7 will improve alignment.

A maximum dial tracking error at any frequency of three-fourths channel division is considered quite satisfactory providing the maximum error at the other two check frequencies is less than one-half dial division. When dial errors somewhat in excess of these values are found, they can frequently be tolerated; in such cases, it is preferable to avoid tampering with the seal of the unit, even though the tracking is not all that might be desired.

Caution: This unit is sealed against moisture. Do not remove the cap unless absolutely necessary.

Should a slug adjustment at 28 megacycles be found necessary, use the following procedure:

- (a) Find as dry a place as possible.
- (b) Run the receiver about an hour with the dust cover in place to warm the unit.
- (c) To remove the cap, heat the single point solder seal of the cap with a soldering iron while exerting a turning motion on the cap.
- (d) Complete the alignment as quickly as possible.
- (e) Replace the cap and re-solder in place.
- (f) If the cap was off for more than five minutes, run the receiver at least an hour with the dust cover in place and the cap off the unit.
- (g) Remove dust cover, replace cap, and re-solder.

c. Radio Transmitter BC-684-A.

(1) *A Change that Should be Made in Existing Equipment: Fuse F101.* Fuse F101 should be of $\frac{1}{2}$ -ampere rating. Some of the early equipment had 1-ampere fuses which do not always give adequate protection. One-half ampere fuses (as supplied in the spare parts groups) should be substituted for any 1-ampere fuses in this position.

(2) Changes in Parts.

(a) *Change in C147.*—The unit used in later production is a ceramic-type capacitor of cylindrical form covered with a black bakelite finish. This is the preferred replacement part. It is specified with plus or minus 2 per cent tolerance and rated at 800 volts, working. If it cannot be obtained it is satisfactory to use the single 175-micromicrofarad unit of the C-D Type 1R capacitor or four 175-micromicrofarad units of the C-D Type 5R capacitor in series-parallel. It is not satisfactory to use a single C-D Type 5R unit.

(b) *Changes in Dynamotor Relay S102.*—This relay has been changed from a Type AO to a Type BO relay with increased contact pres-

sure in the operated position. The latter unit is preferable but either can be used as available.

(c) Change in R107.—R107 was changed from $\frac{1}{2}$ -watt to 1-watt rating at 30,000 ohms in order to care for the higher current taken by some vacuum tubes.

(d) Changes in Resistors R119 and R155.—Two resistors R119 and R155 were originally specified as IRC Type F resistors. The IRC BT or BW types are just as satisfactory at these places and are or may be used interchangeably with Type F. The BT and BW types are preferred, however, because they mount in the transmitter more easily and with less chance of short-circuiting to adjacent parts or the chassis.

(e) Changes in Capacitors C138 and C142.—Capacitors C138 and C142 have been obtained from a number of different manufacturers and therefore it will be found that the "common" terminal (marked c on the capacitor can and in the wiring diagrams) will be located at one end of some capacitors and on the other end of other capacitors. Be careful in replacing a capacitor of this type to see that the c terminal is connected to the proper wires as shown in the wiring diagram of the transmitter.

(f) Changes in Transformers T101 and T102.—Some of these transformers were wound in the reverse direction from the majority. In many instances this will not cause poor operation but in some transmitters a reverse-wound transformer will be indicated by a high noise level on the radio carrier or on the interphone output. This can be cured by reversing (interchanging) the leads (red and blue) to terminals 5 and 6 on transformer T102. Transmitters using reversed transformers will have the wires interchanged at these terminals. Replacement transformers should be checked in this respect.

. (3) Changes in Arrangement.

(a) Change in Connections of C122 and C123 and Addition of L123.—C122 was connected previously from the screen of V104 (power amplifier) to ground. Its ground terminal has been moved to the ungrounded side of the filament of V104. C123 was connected previously

from the ungrounded side of the filament of V104 to ground. It has been changed to connect between ground and the filament of V103. L123 has been added in the filament lead between V103 and V104. The purpose of these changes was to eliminate a tendency to spurious oscillation at very high frequency, which occurred in tube V104 of a few transmitters if a selector button was not depressed.

(b) Change in R118 and Addition of R162 and R163.—R118 has been changed to decrease the power dissipated in it. It was a 30,000-ohm, 2-watt unit, but has been changed to a 100,000-ohm, 2-watt unit, shunted by two other similar units (R162 and R163) mounted in the same resistance group. Thus the total resistance of the combination is not greatly changed but the power capacity is substantially increased. If a field replacement becomes necessary, it is desirable to use three 100,000-ohm, 2-watt units if possible. If they are not available a single 30,000-ohm, 2-watt unit may be used until the 100,000-ohm, 2-watt units can be obtained.

(c) Change in R102 and R107 and Addition of R160.—Some manufacturing variations caused the total current through dropping resistors R102 and R147 to exceed the allowable dissipation in these resistors. The later production units, therefore, were changed to add another resistor, R160, so that the three resistors could reliably dissipate the maximum heat. The total resistance of the three units was kept the same by reducing R102 and R147 from 1000 ohms each to 667 ohms each. R160 is 667 ohms.

(d) Change in R111 and Addition of R161.—R111 was changed from 15,000 ohms to 30,000 ohms, and R161 (30,000 ohms, 1 watt) was added in parallel to care for the increased grid current occurring with some tubes.

(e) Change in L106, L107, C111, C112, and Addition of C164.—During production it was found that some variations in wiring caused the coupling between L106 and L107 to be decreased below a suitable value. This was corrected by interchanging the coils and adding C164. The wiring changes are shown in the wiring diagram, Fig. 75. In the revised circuit some

of the coupling is obtained by mutual inductance between the two coils and additional coupling is obtained by the capacitor network C164, C111, and C112. It will be noted in the wiring diagram that in order to assure satisfactory operation, the leads to C111, C112, and C164 must be held to the length indicated. The tolerances of these capacitors must be held to those shown in Paragraph 45, Table of Replaceable Parts. If these capacitors are properly placed as shown by the wiring diagram and the leads correctly dimensioned, there should be no trouble in making this change in the field. This change need not be made in transmitters which are operating satisfactorily.

(f) Change in Wiring of R109.—One end of R109 was formerly connected to the bottom terminal of L106. This connection was moved in later transmitters to terminal 6 of VS108 in order to reduce the current through resistor R157.

(g) Shortening of Studs E and F and Relocation of L117-R149.—In the early production these studs were longer than necessary. This excess length produced coupling which caused poor oscillator operation in a few cases. Along with the shortening of the studs there were some wiring changes which are discussed in paragraph (3) following. The arrangements can be visualized by reference to Figs. 50 and 75. If this change is found necessary it will be facilitated by inspection of a late model transmitter as a guide. The steps in making the change are as follows:

(1) On stud F, interchange the top and bottom halves of the stud insulator and clip off the unnecessary part of the stud at the under side.

(2) On stud E, interchange the top and bottom halves of the stud insulator and clip off the unnecessary part of the stud at the under side.

(3) The coil-resistor combination (L117-R149) was previously connected from the end of stud E to R101 (the end away from the chassis). It crossed L102 on the side away from the chassis. This unit should be reconnected from the shortened stud E to R101—the end

nearest to the chassis. The wire previously connected to that end of R101 should be removed and reconnected to R101 at the end away from the chassis. With this rearrangement the coil-resistor combination passes between the chassis and coil L102.

(4) The two wires coming to L102 should be interchanged.

(h) Arrangement of Thermocouple Connections.—In order to permit adjusting the antenna current (TUNE-ANT CUR) meter reading over a wider range, the slide-wire adjustment was removed from between the terminals of the thermocouple and placed between the ends of the short coaxial transmission line connecting the antenna relay and the antenna binding post (A) on the front panel of the transmitter. This change cannot be made unless the replacement metering length of coaxial line is available. In installations where the antenna current reading on M101 is too low for convenient use, the reading may be raised by unsoldering the thermocouple slider tap and moving the tap to increase the reading. Take care that the antenna current reading will not go off scale under the highest voltage conditions. If the antenna current reading is too high, the direction of change should be reversed. This adjustment is most effective with the newer type arrangement of the thermocouple circuit.

(i) Meters and Thermocouples.—Meters from three manufacturers and thermocouples from two manufacturers have been used in the transmitters in order to maintain production when the meter or thermocouple from any one manufacturer became temporarily unavailable. Any of the meters and thermocouples will operate satisfactorily in a transmitter although there may be an inconsequential difference in meter readings when different meters are substituted, and the slide-wire tap may need slight adjustment when different thermocouples are substituted. The Weston thermocouples are somewhat faster in operation than the vacuum type marked with a number (ES-680241-7). The Weston meter originally had three connection studs, the two top ones going to the meter movement, the lower one going to the scale plate and magnet.

The lower stud is not and should not be used (see the wiring diagram, Fig. 75). In later meters this third stud has been eliminated. During the change-over from three to two studs, a number of the meters (about 1000) were incorrectly constructed to include a strap connection from the moving coil to the magnet and scale plate. This does not affect its operation at the TUNE position of D121 nor its operation with vacuum thermocouples for ANT CUR position of D121. However, in some transmitters a Weston meter having the incorrect connection may not operate properly with a Weston thermocouple. This will be indicated by very sluggish action of the meter when the antenna trimmer (usually at the highest frequency) is tuned. The meter reading will not drop to low values as it should when the antenna circuit is detuned by the trimmer. The approximately 1000 transmitters which have the incorrectly wired meter are satisfactory because they are equipped with vacuum thermocouples. When a Weston thermocouple is to be substituted for a vacuum thermocouple, tests as mentioned should be made to check the operation of the thermocouple-meter combination. If the trouble appears to be present, three methods of correction are available.

(1) Use a vacuum thermocouple if available; or

(2) Use a Hickok or Triplett meter if available; or

(3) Remove the Weston meter and unscrew and lift off the front portion of the case; open-circuit the connection between the scale plate and moving coil by clipping the strap which runs from the left screw and nut on the moving coil support and under the scale plate to the scale plate screw. Do not remove the nut on the moving coil support as that might cause the moving coil to become incorrectly positioned in its bearings and cause unsatisfactory operation of the meter.

(4) Changes in Values.

(a) Reduction in the Capacitance of C501, C502, C601, and C602.—C501 and C502 in the 12-volt dynamotor have been reduced from

0.003 to 0.002 microfarad. The same is true for C601 and C602 in the 24-volt dynamotor. Either value (0.002 or 0.003 microfarad) is satisfactory, however.

(b) Change in the Voltage Rating of the Postage-stamp Capacitors.—Some of the postage-stamp type of mica capacitors were changed to ones having a higher voltage rating. Capacitors having the voltage ratings shown in Paragraph 45, Table of Replaceable Parts, should be used for replacement purposes. Many capacitors of this type used in sets of early production did not show a designation as to voltage rating. More recently the voltage rating has been color coded, as shown in Paragraph 44. The sixth dot on the capacitor indicates the voltage rating—green for 500 volts, gray for 800 volts, and gold for 1000 volts.

(c) Change in Resistor R106.—R106 has been decreased from 1000 ohms to 100 ohms. The purpose was to keep the meter reading from going off scale when the battery voltage is high and switch D125 is in position 2. The resistor furnished in the spare parts has a resistance of 100 ohms. Replacement of a good existing 1000-ohm unit is not necessary unless the meter reading goes off scale when the battery voltage is high. Since this affects the meter reading you should allow for this when checking the operation of different transmitters.

(5) Elimination and Addition of Parts.

(a) Addition of R159.—R159 was added in later transmitters from the screen of the doubler V103 to ground, in order to make this tube operate more uniformly with wide variations of input voltage.

(b) Elimination of Capacitors C102 and C110.—C102, formerly connected to the filament of V101, and C110, formerly connected to the filament of V102, have been eliminated from the later transmitters. The purpose of this change was to reduce the use of mica capacitors. Either or both of these units may be omitted or removed without impairing the operation of the transmitter.

(c) Elimination of C160.—Capacitor C160 (across the primary of T102) has been

omitted from most transmitters. Some of these capacitors have failed due to surges occurring in the carbon microphone circuit. The omission of this unit in new equipment or removal of it from the existing equipment does not impair the performance of the transmitter. Its removal may cause a slight increase in response at the higher audio frequencies.

(d) Elimination of C107.—This capacitor has been found unnecessary because the units with which it was associated can be held to close tolerances during manufacture.

(e) Elimination of C503 and C603.—These capacitors across the low-voltage end of the 12- and 24-volt dynamotors, respectively, can be eliminated without causing trouble.

d. Changes Affecting All Units. All units of Radio Sets SCR-608-A and SCR-628-A use fasteners to hold covers in place. Most of the units employ Dzus fasteners but a number employ a Shakeproof fastener. Spare Shakeproof fasteners should not be used as replacements on units that have Dzus fasteners and vice versa.

e. Relative Characteristics of Various Types of Capacitors and Resistors. It has been necessary to substitute other types of capacitors in some places where mica units were specified. This has been done where such substitutions do not interfere with satisfactory operation of the radio equipment. In many cases the replacing units differ from the original units in size or

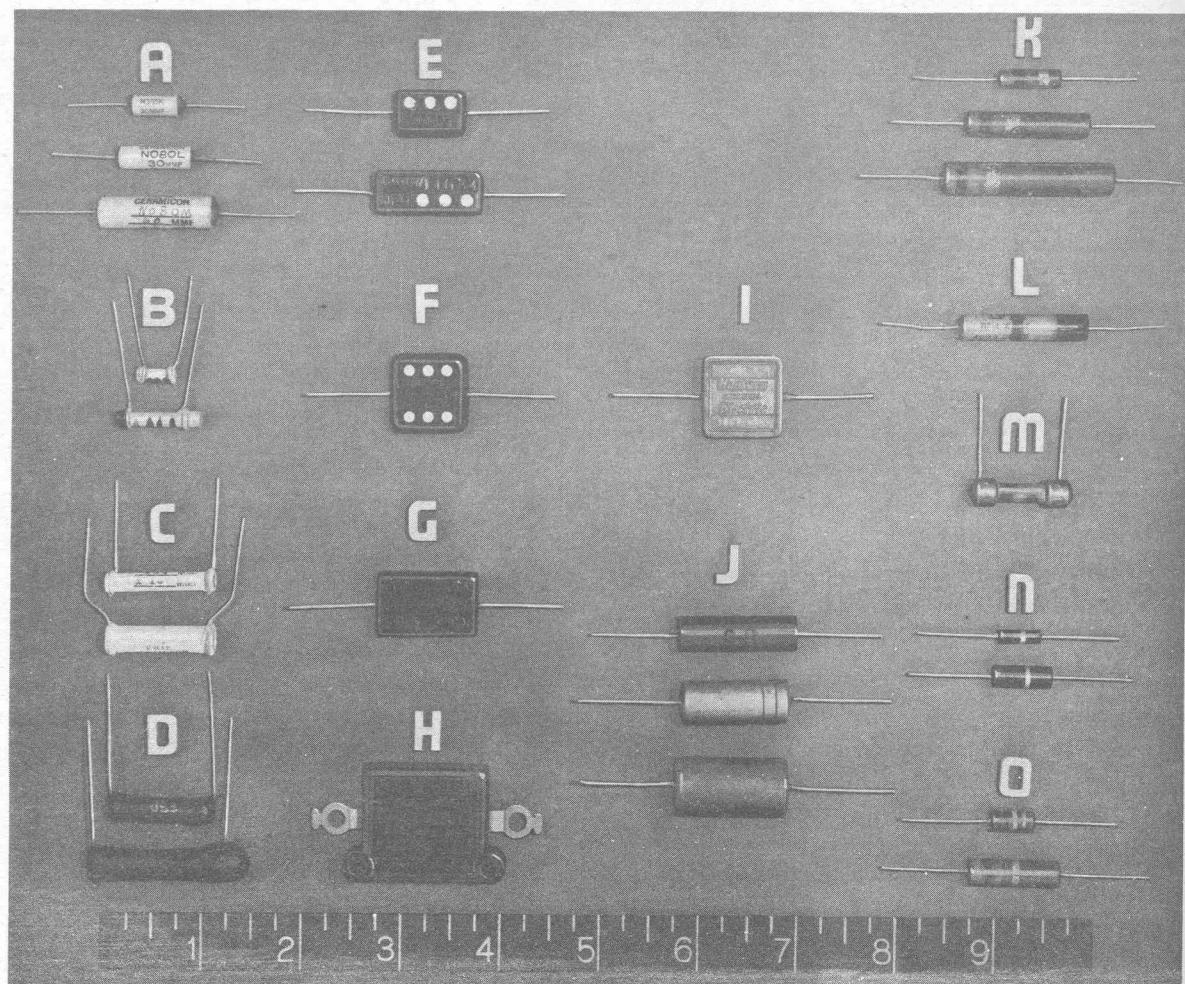

Fig. 63. Types of Capacitors and Resistors

shape or both. The relative appearance of the various capacitors and resistors used in these radio sets is shown in Fig. 63. The first column (A-D) shows ceramic capacitors. The second (E-H) shows mica capacitors and the third (I-J) shows oiled paper capacitors. In the fourth column (K-O) are various kinds of resistors. The general characteristics of such units are given in Table VII and discussed in more detail later. While Fig. 63 covers the range of types, it does not necessarily include all the variations produced by different manufacturers.

The units listed in Paragraph 45, Table of Replaceable Parts, have been selected because

they are the most suitable for the use for which they are specified. Other units, particularly ceramic capacitors, should not be used indiscriminately as replacements.

There are two general types of dielectric (insulation) which are often used in capacitors in place of mica. They are (1) ceramic material and (2) oiled paper. The ceramic capacitor consists of silver fired on ceramic insulation, the composition of the ceramic being varied to obtain different temperature coefficients. These are extremely stable and can be made to cover a wide range of values of temperature coefficients (from plus 120 to minus 750 parts per million

Table VII. Capacitor Characteristics

Group Letter (Fig. 63)	Type	Maximum as Used in This Equipment		Advantages	Disadvantages	Typical Use
		D-C Volts, Working Rating	μμf Capacitance			
First Column	A	Insulated Ceramicon (trade name)	800	200	Stability and choice of temperature compensation	Size limitation for large capacitance; also B, C, and D must not touch metal
	B	Uninsulated ceramic	800	500		
	C	Uninsulated Ceramicon	800	500		
	D	Uninsulated ceramic	800	500		
*Second Column						
E (red)	Insulated silver-mica	800	700	Stability		Tuned circuits
E (brown)	Insulated mica	800	500	Ease of manu- facture		By-pass
F (red)	Insulated silver-mica	1000	1000	Stability		Tuned circuits
F (brown)	Insulated mica	1000	10,000	Ease of manu- facture		By-pass
G (brown)	Insulated mica	1000	10,000	Ease of manu- facture		By-pass
H (brown)	Insulated mica	1200	10,000	Ease of manu- facture		By-pass
*Third Column						
I	Insulated oiled paper	800	10,000	Does not require mica, a critical war material	Not suitable for tuned circuits or large r-f currents	By-pass, replacing F and G
J	oiled paper	800	10,000			

*These capacitors are not obtainable with controlled temperature coefficients.

per degree Centigrade.) For a given size of unit, the capacitance increases as the temperature coefficient becomes more negative. Therefore, no range of capacitance values can be assigned to a particular size without specifying the temperature coefficient. For a given temperature coefficient, the capacitance of a ceramic unit can be increased only by increasing the length or diameter of the tube.

The three sizes shown under group A (Fig. 63) cover the range of physical sizes in which these insulated ceramic capacitors are manufactured. These units were supplied originally in small sizes to provide temperature compensation for the combination of coil and mica capacitor in a tuned circuit. More recently, they have been specified in larger sizes in some tuned circuits to eliminate the need for a mica capacitor and provide temperature compensation for the coil. Since ceramic units with equal capacitance may differ greatly in temperature coefficient, it is not safe to use a ceramic unit for a replacement (where stability is needed) unless the temperature coefficient is known to be correct for that use.

The units illustrated under A and C have the value, tolerance, and temperature coefficient stamped on the unit. The black units shown under D are stamped with the capacitance and a letter signifying the temperature coefficient. Those shown under B are marked with dots in accordance with the color code described in Paragraph 44. Of all these ceramics, the A items are the only ones having adequate insulation to permit installing them where they might touch metal parts. Groups B and C are merely enameled. Group D has a black bakelite coating for moistureproofing but this is not sufficient insulation to permit contact with metal.

Five sizes of ceramic capacitors are shown in Fig. 63. The two smallest are those in B. The next two are those in C, and the largest is the lower unit in D. Except for insulation the largest unit in group A corresponds in characteristics to the small unit in group C.

It will be noticed that with uninsulated ceramic capacitors, the leads are sometimes at

unequal distances from the ends of the unit. The lead which is farther from the end is connected to the outer surface of the capacitor. Whenever possible, this lead should be connected to the ground, or low potential, side of the circuit.

In the conventional type of mica capacitor, strips of metal foil are interleaved between sheets of mica dielectric (insulation). Changes in temperature cause an undesirable amount of variation in the capacitance of such units. The silver-mica unit gives a much more stable capacitor which is suitable for tuned circuits. It consists of sheets of mica with electrodes of silver bonded to each surface.

Groups E and F illustrate the two types of color code discussed in Paragraph 44. Groups E, F, and G are made in both foil-mica and silver-mica units. Group H is used in the transmitter. It is a larger capacitor with higher voltage rating and has a more rigid mounting arrangement.

All the mica capacitors shown in the second column of Fig. 63 are insulated by a molded bakelite jacket and can be allowed to rest against metal. In general, the foil-mica units have a brown jacket, and the silver-mica units have a red jacket. Capacitors with a straw-colored bakelite jacket, as used in this equipment, may be either foil-mica, silver-mica, or paper units.

Ceramic capacitors are used where high stability is necessary and paper capacitors elsewhere whenever possible.

The capacitors shown in the third column of Fig. 63 use oil-impregnated paper for insulation. For stability, they do not compare with silver-mica types but they can be used as replacements for foil-mica types for screen grid and filament positions of vacuum tubes where they do not need to pass much radio-frequency current. In general, they are good substitutes for mica units for most by-pass purposes. The voltage rating decreases as the capacitance increases as follows:

Capacitance (microfarads)	0.003	0.006	0.01
Rating (d-c volts, working)	800	600	400

Group I shows a molded bakelite case which is adequate insulation. In general, such units will be black though they may be straw-colored.

Group J shows tubular-shaped units. The top unit has a thin bakelite cover and may be allowed to touch metal. The second unit in this group has a metal case and may have either one or both leads insulated from this case. If one lead is not insulated, it should be connected to ground or the lower voltage connection. The bottom unit in group J is identical with the second except for a cover which gives some insulating protection but is not sufficient to permit resting the unit against metal.

In summary, the unit specified in the Table of Replaceable Parts for a particular circuit symbol may be different in appearance from the one which it replaces and may require some ingenuity in mounting. Groups I and J are intended to take the place of F and G in some applications. Groups A, B, C, and D replace silver-mica units of groups E, F, and G where stability is required but must be used only as specified because of the wide range of temperature coefficients which they cover. As described in Paragraph 43b(10), sometimes a single ceramic unit is used to replace a silver-mica plus a small ceramic.

The fourth column (groups K-O) shows various small resistors. They vary considerably in size and shape for the same wattage ratings due to differences in manufacture. The units shown in group K are $\frac{1}{2}$ watt, 1 watt, and 2 watts, respectively. They are bakelite-insulated and may touch metal. The unit shown under L is a 1-watt unit. The unit shown at M with side leads is a high-frequency resistor. This has metal ends and is not insulated. This unit is used only in a few places in the transmitter. It is rated at $\frac{1}{2}$ watt. The units shown at group N (brown body) are bakelite-insulated resistors of the $\frac{1}{2}$ - and 1-watt sizes made by another manufacturer. (This manufacturer also makes a similar uninsulated resistor with a black body.) These are directly interchangeable with the upper two units in group K, above. The units shown at O are $\frac{1}{2}$ - and 1-watt sizes from still another manufacturer and are interchangeable with corresponding units already mentioned.

Similar units of other manufacture not shown may be used to replace those illustrated.

44. Color Codes on Components. The various types of capacitors and resistors used in Radio Sets SCR-608-A and SCR-628-A are illustrated in Fig. 63 and discussed in Paragraph 43e. Some capacitors and resistors have their values stamped on the unit, but in many cases colored dots and bands are used instead. The various color codes used for capacitors and resistors are shown in Figs. 64 to 68 inclusive, and are discussed in the following paragraphs.

a. Molded Mica Dielectric Capacitors. Capacitors of this type are illustrated in groups E, F, G, and H of Fig. 63. Three different color codes are used on these units:

The three-dot code.

The RMA (Radio Manufacturers Association) six-dot code.

The AWS (American War Standard) six-dot code.

(1) *Three-dot Code for Molded Mica Capacitors.* This code, which was widely used for a number of years, is gradually being replaced by the other two codes. However, many components so marked are used in Radio Sets SCR-608-A and SCR-628-A. Also, this code is likely to be encountered in parts stocks. As indicated in Fig. 64, the basis of the code is a series of three colored dots which indicate the capacitance, in micromicrofarads, of the unit. Two auxiliary colored dots indicating, respectively, the voltage rating and the capacitance tolerance, are sometimes, but not always, added. There is usually a molded or stamped arrow to show the sequence in which the dots are to be read. Dots one and two indicate the first two digits, while dot three tells the decimal multiplier to be used. Take, for example, a 0.006-microfarad capacitor. Its capacitance in micro-microfarads is 6000; the three dots, in sequence, are: blue (6), black (0), red (100).

The dot indicating the tolerance, when used, is usually located above or below the third (decimal multiplier) dot. As shown in Fig. 64, the various colors correspond to tolerances between plus or minus 1 per cent and plus or minus 20 per cent.

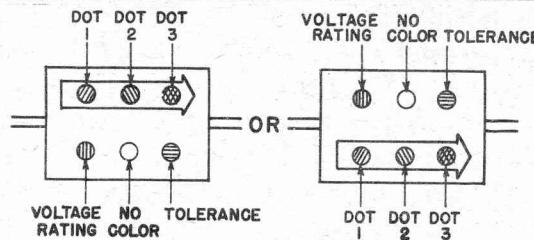

The voltage dot, when used, is ordinarily located above or below the first (first digit) dot. The various colors tell, according to the code of Fig. 64, the d-c working voltage.

When either or both of the auxiliary dots are omitted, it indicates that the capacitance tolerance is plus or minus 20 per cent and that the d-c working voltage is the lowest rating for the particular type and size of capacitor.

(2) *RMA Code for Molded Mica Capacitors.* The RMA (Radio Manufacturers Association) code illustrated in Fig. 65 is used to a limited extent. It uses six colored dots with an arrow to show the sequence. The first three dots give the first three digits of the capacitance in micromicrofarads; the fourth dot (directly below the third) gives the decimal multiplier. The fifth indicates the tolerance in capacitance, and

the sixth, the d-c working voltage. For example: a capacitor of 0.006 microfarad (6000 micromicrofarads) plus or minus 10 per cent, 800 volts d-c, working, would be marked with dots in the following order: blue (6); black (0); black (0); brown (multiplier 10); silver (plus or minus 10 per cent); gray (800 volts).

(3) *AWS Code for Molded Mica Capacitors.* The AWS (American War Standard) code for molded mica capacitors is shown in Fig. 66a. Like the RMA code, it uses six colored dots, but with somewhat different significance. The first four dots give the capacitance in micromicrofarads, as follows: first significant figure; second significant figure; third significant figure; decimal multiplier. It will be noted that this scheme makes provision for marking units in three significant figures. For example, consider a capaci-

Color	First Dot		Second Dot		Third Dot		Tolerance	Voltage Rating
	First Digit	Second Digit	Second Digit	Decimal Multiplier				
Black	0	0		1			$\pm 20\%$	
Brown	1	1		10			$\pm 1\%$	100
Red	2	2		100			$\pm 2\%$	200
Orange	3	3		1,000			$\pm 3\%$	300
Yellow	4	4		10,000			$\pm 4\%$	400
Green	5	5		100,000			$\pm 5\%$	500
Blue	6	6		1,000,000			$\pm 6\%$	600
Violet	7	7		10,000,000			$\pm 7\%$	700
Gray	8	8		100,000,000			$\pm 8\%$	800
White	9	9		1,000,000,000			$\pm 9\%$	900
Gold	—	—		0.1			$\pm 5\%$	1,000
Silver	—	—		0.01			$\pm 10\%$	2,000
Body	—	—		—			$\pm 20\%$	*

*When no color is indicated, the voltage rating may be as low as 300 volts.

Fig. 64. Molded Mica Capacitors: Three-dot Color Code

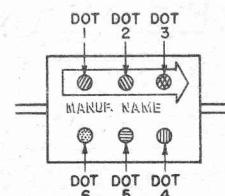

tor of 1,250 micromicrofarads. With the AWS code, the 1,250-micromicrofarad capacitor would be marked: brown (1), red (2), green (5), brown (10); the precise value of 1,250 micromicrofarads would thus be shown by the color code.

In practice, the precision markings just described are seldom necessary. In fact, none of the capacitors standardized under the AWS code requires more than two significant digits to specify its capacitance. For example, molded-mica-dielectric capacitors of the size known as "CM30" are standard in capacitances of 1000, 1100, 1200, 1300, 1500, 1600, etc., micromicrofarads. Intermediate values, such as 1,250 or 1,530, are not at present incorporated in the code. This is taken advantage of, as follows: The first dot on all capacitors now standard is black (0), and the two necessary significant figures are given by the second and third dots. The black first dot thus becomes a distinguishing feature or identification symbol, as it were, for a capacitor marked according to the AWS code. A couple of examples may serve to make this clear. Take, first, a 120-micromicrofarad capacitor; it is marked: black (0); brown (1); red (2); brown (10)—0120 micromicrofarads.

Or, consider a 9,100-micromicrofarad capacitor: black (0); white (9); brown (1); red (10)—09100 micromicrofarads. It will be noticed that in both these instances the first dot is black.

The fifth dot in the AWS code indicates the capacitance tolerance in per cent of nominal capacitance. The sixth dot indicates the design characteristic, as indicated in Fig. 66a, is the temperature coefficient. For example a 0.006-microfarad (6000 micromicrofarads) plus or minus 10 per cent mica by-pass capacitor would be marked: black (0); blue (6); black (0); red (100); silver (plus or minus 10 per cent); black (mica by-pass, with no temperature coefficient specified).

It will be noted that this color code does not include the voltage rating. This is considered

Color	First Dot		Second Dot		Third Dot		Fourth Dot	Decimal Multiplier	Fifth Dot	Tolerance	Sixth Dot	Voltage

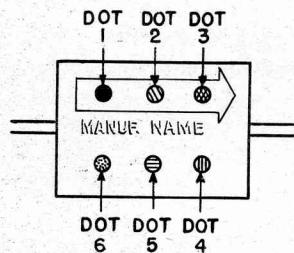

Fig. 65. Molded Mica Capacitors: RMA Six-dot Color Code

unnecessary, since with few exceptions, all capacitors marked with this color code are rated at 500 d-c working volts. The exceptions, all of which are rated at 300 volts, are:

Type CM35 capacitors (53/64-inch maximum length) with capacitances of 6,800, 7,500, and 8,200 micromicrofarads.

Type CM40 capacitors (1-1/32 inch maximum length) with capacitances of 9,100 and 10,000 micromicrofarads.

Further details of the American War Standard for fixed-mica-dielectric capacitors will be found in Standard C75.3 of the American Standards Association.

b. Molded Paper Dielectric Capacitors. A new AWS color code for small molded paper dielectric capacitors is shown in Fig. 66b. Although this code has found little application to date, it is possible that some units so marked may be encountered in future equipment or stocks. Like the code for mica capacitors just discussed, it employs six colored dots, together with an arrow to indicate the sequence. Units marked according to this system can readily be identified by the fact that both the first and fifth dots are always silver. The other dots are used as follows: the second dot gives the first digit of the capacitance in micromicrofarads; the third dot gives the second significant figure; the fourth dot indicates the decimal multiplier; the sixth tells whether the unit has a maximum operating temperature of 167 degrees or 185 degrees Fahrenheit.

No indication of the working voltage is given by the color code. In general, it can be said that molded paper dielectric capacitors meeting the AWS specification have d-c working voltages be-

Color	First Dot	Second Dot	Third Dot	Fourth Dot	Fifth Dot	*Sixth Dot

White	—	9	9	0.1	±10

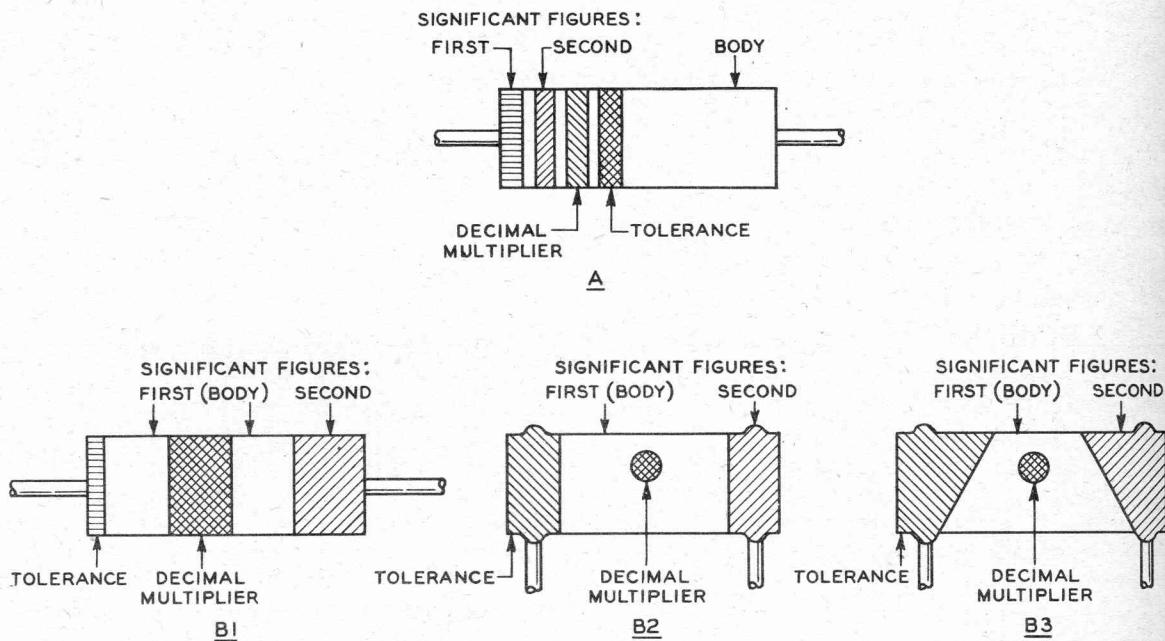

*The temperature coefficient is expressed in micromicrofarads per micromicrofarad per degree Centigrade. Some capacitors are marked with a numeral instead of a color code; for example, N-030 represents 0.00003 neg.

†Tolerances for capacitors of 10 micromicrofarads or less are expressed in tenths of a micromicrofarad instead of percentages.

Fig. 67. Tubular Ceramic Capacitors: RMA Color Code

tween 300 and 800 volts. The lower voltage applies to units with high-capacitance ratings; the higher voltage applies to units with low-capacitance ratings. Further details will be found in Standard C75/221 of the American Standards Association.

c. Tubular Ceramic Dielectric Capacitors. Tubular ceramic dielectric capacitors, which are widely used for temperature compensation, are sometimes marked according to the RMA color code shown in Fig. 67. As will be seen from the figure, the negative temperature coefficient is in-

Color	First Significant Figure	Second Significant Figure	Decimal Multiplier	Tolerance
Black	0	0	1	—
Brown	1	1	10	± 1%
Red	2	2	100	± 2%
Orange	3	3	1,000	± 3%
Yellow	4	4	10,000	± 4%
Green	5	5	100,000	± 5%
Blue	6	6	1,000,000	± 6%
Violet	7	7	10,000,000	± 7%
Gray	8	8	100,000,000	± 8%
White	9	9	1,000,000,000	± 9%
Gold	—	—	0.1	± 5%
Silver	—	—	0.01	± 10%
No color	—	—	—	± 20%

Fig. 68. Fixed Resistors: RMA and AWS Standard Color Codes

dicated by the color of the band or tip at one end of the unit; the capacitance in micromicrofarads is shown by the first three dots; the capacitance tolerance, either in per cent or tenths of a micro-microfarad, depending upon the size of the unit, is indicated by the fourth and last dot. Example: a 30-micromicrofarad plus or minus 5-per-cent capacitor with a negative temperature coefficient of 80 parts per million per degree Centigrade would be marked as follows: tip, red (-80); first dot, orange (3); second dot, black (0); third dot, black (1); fourth dot, green (plus or minus 5 per cent).

d. Fixed Resistors. Small fixed resistors, both composition-type and wire-wound, are frequently marked with colored bands and dots to indicate the resistance and tolerance. Two color codes are widely used: the RMA and the AWS. The two codes are not identical in all particulars, but they are similar in many respects. One chart, applicable to both, is shown in Fig. 68. It will be seen that in all cases the various combinations of body color, bands, and dots indicate the resistance to two significant figures (the first two digits), the decimal multiplier, and the per cent tolerance in resistance.

As illustrated by Fig. 68, two basic methods are used for indicating the resistance and tolerance:

Method A. This uses four colored bands, starting at one end of the unit, to show resistance and tolerance. The bands, reading from left to right, indicate: first significant figure; second significant figure; decimal multiplier; per cent tolerance. (The significance of

the body color under this method will be explained later.)

Method B. Several variations of this method are in use (B1, B2, B3 of Fig. 68). With all of these, however, the interpretation of the code is practically the same: left end, tolerance; body, first significant figure; right end, second significant figure; central dot or band, decimal multiplier.

To illustrate the basic schemes, consider a 5,600-ohm ± 10 -per-cent fixed resistor. It would be marked:

Method A. First band, green (5); second band, blue (6); third band, red (100); fourth band, silver (± 10 per cent).

Method B. Left end, silver (± 10 per cent); body, green (5); right end, blue (6); central band or dot, red (100).

In Method A, where the body color plays no part in indicating resistance or tolerance, it may be used to indicate the type of resistor unit. Under the RMA code, a black body is frequently used to indicate an uninsulated composition unit; a tan, olive, or white body, an insulated composition unit; and a dark brown body, an insulated wire-wound unit. The AWS code requires that an uninsulated unit using Method A have a black body; the body of an insulated unit may be any color, although a natural tan is preferred.

When there is doubt as to whether a particular resistor is composition or wire-wound, it is well to remember that any resistor of 100 ohms or less is very likely to be wire-wound—also, to remember that it may be wound inductively.

45 TABLE OF REPLACEABLE PARTS (TABLE IX).

NOTE: The list of stock numbers is intended to supplement the Signal Corps General Catalog until such time as the catalog is revised to include the stock numbers in this table. Order replacement part by stock number and description.

Reference Number	Signal Corps Stock Number	Name and Description of Part	Mfr's. Code and Type Number	Function	Mfr's. Code and Type Number	Contractor's Drawing Number
a. Radio Receiver BC-683-A:

j. List of Manufacturers (Table IX).

Mfr's. Code	Name	Address
A-B	Allen-Bradley Co.	136 West Greenfield Avenue, Milwaukee, Wis.
Allied	Allied Control Co.	227 Fulton Street, New York, N.Y.
Amphenol	American Phenolic Corporation	1250 Van Buren Street, Chicago, Ill.
Cannon	Cannon Electric Development Co.	420 West Avenue 33, Los Angeles, Calif.
C-D	Cornell-Dubilier Electric Corp.	South Plainfield, N.J.
Diamond	Diamond Expansion Bolt Co.	Garwood, N.J.
Drake	Drake Manufacturing Co.	1713 West Hubbard Street, Chicago, Ill.
Dzus	Dzus Fastener Co., Inc.	Babylon, N.Y.
Erie	Erie Resistor Corporation	Erie, Pa.
G.E.	General Electric Co.	Schenectady, N.Y.
H&H	Arrow-Hart & Hegeman Electric Co.	Hartford, Conn.
IRC	International Resistance Co.	403 North Broad Street, Philadelphia, Pa.
Isolantite	Isolantite, Incorporated	233 Broadway, New York, N.Y.
Jensen	Jensen Radio Manufacturing Co.	6601 South Laramie Avenue, Chicago, Ill.
Jones	Howard B. Jones	2300 Wabansia Avenue, Chicago, Ill.
Littelfuse	Littelfuse, Inc.	4757 Ravenswood Avenue, Chicago, Ill.
Mallory	P. R. Mallory & Co., Inc.	Indianapolis, Ind.
Muter	Muter Company	1255 South Michigan Avenue, Chicago, Ill.
National	National Company	Maliden, Mass.
N.Y. & N.J.	New York and New Jersey Lubricant Co.	300 Delancey Street, Newark, N.J.
Oak	Oak Manufacturing Co.	1260 Clybourn Avenue, Chicago, Ill.
Ohmite	Ohmite Manufacturing Co.	4837 Flournoy Street, Chicago, Ill.
RCA	RCA Manufacturing Co., Inc.	Harrison, N.J.
Spencer	Spencer Thermostat Co.	Attleboro, Mass.
United	United-Carr Fastener Corp.	Cambridge, Mass.
USR	United States Rubber Co.	191 Hudson Street, New York, N.Y.
WE	Western Electric Co., Inc.	120 Broadway, New York, N.Y.
W-L	Ward-Leonard Electric Corp.	32 South Street, Mount Vernon, N.Y.
Weston	Weston Electrical Instrument Corp.	618 Freylinghuysen Avenue, Newark, N.J.
Zierick	Zierick Manufacturing Co.	385 Gerard Avenue, New York, N.Y.

- NOTES**
1. WIRES MARKED "A" ARE FURNISHED WITH APPARATUS.
 2. WIRES MARKED "B" ARE NO. 16 A.W.G.A. TINNED.
 3. WIRES MARKED "C" ARE NO. 18 A.W.G.A. TINNED.
 4. WIRES MARKED "D" ARE NO. 16 AW.GA. STRANDED 1250 VOLT RADIO HOOK-UP WIRE.
 5. WIRES MARKED "E" ARE NO. 20 A.W.G.A. SOLID 1250 VOLT RADIO HOOK-UP WIRE SHIELDED.
 6. WIRES MARKED "F" ARE TRANSMISSION LINE.
 7. WIRES MARKED "G" ARE NO. 20 AW.GA. STRANDED 1250 VOLT RADIO HOOK-UP WIRE.
 8. WIRES MARKED "H" ARE FLEXIBLE 1/4 IN. COPPER STRIP.
 9. WIRES MARKED "J" ARE TINNED COPPER BRAID 1/4 IN. WIDE.
 10. WIRES MARKED "L" ARE NO. 22 AW.GA.
 11. WIRES MARKED "N" ARE NO. 10 AW.GA. STRANDED 1250 VOLT RADIO HOOK-UP WIRE.
 12. WIRES MARKED "P" ARE NO. 22 AW.GA. T WIRE.
 13. WIRES MARKED "I" ARE IN CABLE NO. I.
 14. WIRES MARKED "2" ARE IN CABLE NO. 2.
 15. ALL OTHER WIRES NOT MARKED ARE NO. 20 AW.GA. SOLID 1250 VOLT AEROGLOSS RADIO HOOK-UP WIRE.
 16. ALL WIRE IS WHITE BACKGROUND. COLORS SPECIFIED ARE TRACER COLORS.
 17. AT PG 101 AND J 101 PLACE A 7/8 INCH LENGTH OF YELLOW FLEXIBLE VARNISHED CAMBRIC TUBING OVER WIRE, SOLDER WIRE TO TERMINAL, AND SLIP THE TUBING OVER SOLDERED JOINT UNTIL IT BEARS AGAINST BACK FACE OF JACK OR RECEPTACLE. USE NO. 11 TUBING FOR SMALL WIRES AND NO. 4 TUBING FOR LARGE WIRES OR WHERE TWO WIRES ARE CONNECTED TO THE SAME TERMINAL.
 18. WHERE 3 OR MORE WIRES WHICH ARE NOT SEWN INTO THE CABLE RUN PARALLEL THEY SHALL BE TIED TOGETHER AT APPROXIMATELY ONE INCH INTERVALS IN ORDER TO HOLD THEM NEATLY AND SECURELY IN PLACE.
 19. EACH WIRE END SHALL BE WRAPPED AROUND THE TERMINAL TO WHICH IT CONNECTS FOR AT LEAST ONE FULL TURN, CRIMPEQ TO TERMINAL, THEN NEATLY SOLDERED; EXCEPT AT PG101 AND J101 WHERE THE WIRES MUST ENTER THE END OF THE TERMINALS FOR AT LEAST 1/8 INCH AND THEN NEATLY AND SECURELY SOLDERED. CARE SHALL BE USED TO PREVENT SOLDER FROM RUNNING INTO TUBE SOCKET PIN CLIPS.
 20. BARE WIRES, EXCEPT THOSE RUNNING DIRECTLY TO A GROUND LUG, MUST CLEAR ALL ADJACENT WIRES AND APPARATUS BY AT LEAST 1/8 INCH, AND MUST BE SO FORMED AS TO PREVENT CONTACT BEING MADE DURING THE NORMAL MOVEMENT OF ANY ADJACENT ITEM OR PART.
 21. INCORPORATE BENDS IN "B" WIRES TO LI03A, LI04 AND LI05A TO RELIEVE VIBRATION STRESS ON TERMINALS.
